and compared them to diabetics who did not require insulin. Patients requiring insulin can be considered to have more severe diabetes and have a greater chance of experiencing elevated blood glucose in the perioperative period, Dr. Waddell said.

For the new study, Dr. Waddell and his colleagues reviewed the medical charts of 773 men and women who had undergone total hip or knee replacement between 2011 and 2016. Of those, 437 had been diagnosed with insulin-dependent diabetes, while 336 had not been diagnosed with the condition.

Patients with insulin-dependent diabetes were more than five times as likely as those without the condition to develop hyperglycemia, or [high blood sugar](#), after surgery (odds ratio, 5.2; P

People with diabetes who undergo joint replacement surgery are at sharply higher risk of experiencing elevated blood sugar after the operation, increasing their chances of developing infections and other complications, according to a new study by researchers at Hospital for Special Surgery (HSS) in New York City and The Ochsner Health System in New Orleans.

Previous studies have shown that high blood sugar, or hyperglycemia, during the perioperative period of orthopedic [joint replacement surgery](#) is a risk factor for infection. The new study, by Bradford Waddell, MD, a hip and knee surgeon at HSS, took a narrower look at the question. It included patients with a diagnosis of diabetes whose blood sugar was being controlled using the [hormone insulin](#)
