in gastric lesions with premalignant potential.

These findings provide further insight into the detrimental events that develop in response to *H. pylori* infection.

More information: Lydia E. Wroblewski et al. Targeted mobilization of Lrig1+ gastric epithelial stem cell populations by a carcinogenic *Helicobacter pylori* type IV secretion system, *Proceedings of the National Academy of Sciences* (2019). [DOI: 10.1073/pnas.1903798116](https://doi.org/10.1073/pnas.1903798116)

Helicobacter pylori infects approximately half of the world's population and is the strongest known risk factor for developing gastric cancer. Gastric cancer is the third most lethal cancer worldwide.

A cluster of genes called the "cag pathogenicity island" renders some strains of *H. pylori* particularly virulent. However, it is not clear exactly how *H. pylori* induces gastric cancer.

Now in a study published in the *Proceedings of the National Academy of Sciences*, Lydia Wroblewski, Ph.D., Richard Peek, MD, and collaborators have shown that in chronically infected mice, carcinogenic strains of *H. pylori* mobilize a [transmembrane protein](#) that marks a distinct population of progenitor cells called Lrig1.

H. pylori was found to stimulate Lrig1-expressing progenitor cells in a cag-dependent manner, and these reprogrammed cells gave rise to a full spectrum of differentiated cells. Moreover, in human samples, Lrig1 expression was enhanced
