Telemedicine reduces mental health burden of COVID-19

24 March 2020

"The Role of Telehealth in Reducing the Mental Health Burden from COVID-19" has just been published in the peer-reviewed journal *Telemedicine and e-Health*.

In the article by Xiaoyun Zhou and coauthors, substantial evidence supports the effectiveness of telemental health in the areas of depression, anxiety, and post-traumatic stress disorder (PTSD). Factors such as fear of exposure, isolation, loss of income, reduced autonomy, and the absence of a cure for coronavirus infection are contributing to increased stress. The authors emphasize that the provision of mental health support, especially via telehealth, will help patients maintain their psychological well being.

"Telemedicine, which includes telehealth, is growing exponentially at all healthcare institutions, as well as for physicians in groups and in private practice. Healthcare executives are preparing for this," says Mary Ann Liebert, president and CEO of the company that bears her name.
