When a handgun is in the home, suicide risk quickly rises
4 June 2020, by Amy Norton

Handgun owners are at substantially heightened risk of suicide in the years after buying their first gun, a large new study finds.

The study of more than 26 million California residents found that first-time handgun owners were nearly four times more likely to die by suicide in the coming years versus non-owners.

Their risk of suicide by firearm, specifically, rose to a striking degree: Male handgun owners had an eight times higher risk, versus other men; the risk soared 35-fold among female gun owners, compared with other women.

That partly reflects the fact that women generally have a low rate of suicide by gun, said lead researcher David Studdert. And, in fact, he said, men accounted for the large majority of firearm suicides during the study period, at 83%.

However, the findings add to a body of evidence linking gun ownership to suicide risk among both men and women.

"It's one of the most common, and one of the strongest, risk factors for suicide," said Studdert, a professor of medicine and law at Stanford University.

But while past studies have uncovered the connection, many have been relatively small. In contrast, the current study followed millions of Californians for an average of seven years, and up to 12 years.

It also helps address what Studdert called a "common critique" of past research: Some have argued that certain people buy guns with the intent to kill themselves—and that is what explains the gun-suicide association.

In this study, the risk of suicide by firearm did indeed "peak" immediately after the handgun purchase. But, Studdert said, 52% of all those suicides among handgun owners occurred more than a year after the purchase.

Those findings on "timing of risk" are important, said Daniel Webster, a professor at Johns Hopkins University and director of its Center for Gun Policy and Research.

"This suggests there's a subset of people who are intent on suicide, and decide to end their lives with a gun," said Webster, who was not involved in the study. "But this high risk extends for a long period. That suggests there are many people who were not suicidal when they bought the gun."

Studdert and his colleagues reported the findings in the June 4 issue of the New England Journal of Medicine.

Americans own more guns than civilians in any other country, the researchers pointed out. Meanwhile, the United States also has one of the...
highest rates of suicide by gun in the world.

Yet the issue gets relatively little attention, Studdert
said.

Firearm homicides—particularly mass
shootings—garner widespread media coverage, and
much of the focus in debates over gun control. But
two-thirds of U.S. deaths that involve guns are
actually suicides, Studdert said.

Statistics like those have experts worried in the
current social context. Since the COVID-19
pandemic hit U.S. shores, data show that gun
purchases are up, Webster noted—though it’s not
clear how many of those are first-time buys.

But the mix of unemployment, social isolation,
emotional distress and easy access to guns is
obviously ominous.

"We’re worried," Webster said. "And anyone who
studies suicide is concerned."

The current findings are based on California state
data on handgun transfers and mortality records.
During the study period, more than 1.4 million
people died, including nearly 17,900 suicide
deaths. Almost 6,700 involved a gun.

A firearm was used in 89% of suicide deaths
among handgun owners, versus 33% among non-
owners.

According to Webster, a myth persists that "guns
don't matter" and a person intent on suicide will find
another way. But, he said, statistics show that when
people survive a suicide attempt, they usually get
help and do not attempt it again.

Guns are so highly lethal, they rarely allow people
to have that chance, Webster said.

There is evidence that gun policies can help
prevent suicides. They include waiting
periods—which may keep a gun out of the hands of
someone intent on suicide—and stricter licensing
requirements, Webster added.

And preliminary evidence suggests benefits from so-
called "red flag" laws—which allow civil courts to
order a temporary removal of firearms from people
believed to be at imminent risk of harming
themselves or others.

A number of U.S. states have enacted such laws,
and Studdert said recent research has turned up
"encouraging signs" that they can reduce firearm
suicides.
