Type III interferons: Protective or harmful in COVID-19?

12 June 2020

"Our data indicate that SARS-CoV-2 inhibits interferon production in the upper airways, weakening the immune response and helping the virus survive," says senior investigator Ivan Zanoni, Ph.D., an immunologist at Boston Children's. "But when the virus reaches the lower airways, there is an exuberant immune response, including upregulation of type III interferons that we think is harmful."

The team first tested samples from patients with severe COVID-19 and healthy controls. Interferon III was not much increased in the patients' nasopharyngeal swab samples, but was markedly elevated in their lung fluid.

The researchers then exposed mice to synthetic viral RNA to mimic the effects of SARS-CoV-2 infection in the lower airways. They showed that interferon III levels rose markedly in the animals' lungs as compared with control mice, and that sustained production of interferon III prevented the lungs from maintaining their protective surface barrier. This, in turn, made the animals more susceptible to lethal bacterial infections from Staphylococcus aureus: experiments showed increased amounts of bacteria and higher mortality as compared with control mice.

"There's still a lot to understand, but it looks like location and timing of interferon production are key," says Zanoni. "Early during SARS-CoV-2 infection, when the virus is in the upper airways, it might be important to intervene with recombinant interferons and other antivirals. But later on, when inflammation is highly increased in the lower airways, it will be important to block the signaling cascade initiated by interferons and other inflammatory cytokines, possibly with the anti-inflammatory drugs."
