American rapper Kanye West has been making headlines recently as he

mounts a campaign to be elected president of the United States.

We've seen a series of chaotic and emotional public outbursts, including during his first [presidential campaign appearance](#), as well as a string of [incoherent tweets](#) which he subsequently retracted.

Although the journey from celebrity to high public office is no longer implausible, it is tempting simply to dismiss West's outbursts as yet another display of 21st-century narcissism.

But he suffers from [bipolar disorder](#), so it's important we understand his behavior in the context of his mental illness.

What is bipolar disorder?

[Bipolar disorder](#), previously known as manic-depressive illness, involves [alternating periods](#) of intense mania (high energy and activity) and [severe depression](#) (low energy and mood).

Manic periods, which can last days to weeks, are associated with:

- an intense internal drive to be active and inability to sit still
- grandiose ideas and motivation to achieve big things
- fast speech that's difficult to interrupt
- poor sleep
- a strong sense of oneness with the world
- irritable or elated moods.

When these periods are less severe or shorter, it's typically referred to as hypomania.

West's recent public behavior indicates he may have been experiencing a [hypomanic period](#).

Depressed periods, which often last weeks to months, are associated with:

- overwhelming fatigue
- low moods
- suicidal thoughts and behaviors.

We also see mixed states, where the person is very active or agitated but simultaneously very distressed.

And as the illness is characteristically episodic rather than persistent, many people with bipolar disorder have long periods of being well and productively engaged with their families, work and wider society.

Who does bipolar disorder affect, and what causes it?

The illness typically has its onset [during adolescence](#), and goes on to affect about [1% of the adult population](#). It runs [strongly in families](#) and occurs equally [in men and women](#).

Less severe forms of the illness, often termed bipolar II or bipolar spectrum [disorders](#), have less intense manic periods (hypomania) as well as unstable or depressed mood, and may affect [a further 2-3%](#) of adults.

While classified descriptively as "mood disorders", it's more likely these disorders represent a failure of the internal body (circadian) clock to stay in close synchronisation with our normal 24-hour light/dark and activity/sleep cycles.

Some researchers have proposed this failure of the [internal circadian system](#) to maintain strong rhythms is the true cause of bipolar disorder.

Indeed, switches from normal daily rhythms to manic periods [commonly](#)

[occur](#) with seasonal changes in autumn and spring, when the day length (and period of light exposure) varies most rapidly.

This sits well with [recent evidence](#) showing regular exposure to daylight has profound effects on the motor behavior and moods of diurnal (active during daylight) mammals.

Similarly, other factors that disrupt the [normal sleep-wake cycle](#) can precipitate episodes, such as international travel, rotating shift-work, stimulant drugs and childbirth.

But we still have a lot more to learn about what causes bipolar disorder and what sparks the manic episodes that come with it.

Can bipolar disorder be treated?

Untreated bipolar disorder can have adverse effects on a person's life, including on their relationships and capacity to participate in society. But the condition can be treated.

In the late 1940s, Australian psychiatrist John Cade made one of the most remarkable therapeutic discoveries in [modern medicine](#): [lithium carbonate](#). Lithium continues to be used today as a "mood stabiliser" for people with bipolar disorder.

Lithium has been shown to induce a unique state of calming without sedation in hypomania or mania, prevent recurrence of further manic episodes and [reduce suicidal behavior](#).

But not everyone responds to lithium, and it does have [side effects](#). In high doses, it's toxic to the brain, while in therapeutic doses it may cause tremor, thirst, urination, diarrhea, nausea, acne and reduced thyroid function.

One of lithium's primary effects is [stabilization of the circadian \(body\) clock](#), probably via its direct biochemical impact on the molecular machinery in the brain. This has created interest in what other medical, psychological and behavioral therapies may achieve the same result—ideally with less risk.

Today, a range of other agents that stabilize brain function (most notably [anti-epileptic compounds](#) such as carbamazepine, sodium valproate and lamotrigine) or target the brain's circadian clock (by mimicking the normal night-time release of the sleep hormone melatonin) are also used.

Often, providing [effective treatment](#) for the depressive phase is the most challenging. Many [common antidepressant drugs](#) are less effective for bipolar disorder, or may lead to further mood instability.

Importantly, all medicines should be combined with key behavioral features like regular work and social rhythms, daily exercise, morning light exposure and regular sleep patterns to have the greatest effects. Psychological therapies may also play a role.

Creative, perceptive, driven

People with [bipolar disorder](#), often between episodes of illness or when receiving effective treatments, have been frequently observed to be [highly creative](#), socially sensitive, exquisitely perceptive, remarkably lucid, and having strong drive to pursue collective social goals.

When we encounter public displays like West's, before rushing to judgment, we need to take a little more time to consider the experience of the person at the center of the media storm, and the effects on their family. His wife [Kim Kardashian West](#) has implored compassion.

We still have a long way to go before we can really appreciate the

challenges of living with bipolar or any other major mental disorder.
