

# Prenatal depression alters child's brain connectivity, affects behavior

10 August 2020

Prenatal depression symptoms were associated with weakened white matter tracts in the cingulum (left) and amygdala pathway (right). Credit: Hay et al., *JNeurosci* 2020

dysregulated emotional states in the children and may explain why the children of depressed mothers have a higher risk of developing depression themselves. The weakened white matter was associated with increased aggression and hyperactivity in the male children. These findings highlight the need for better [prenatal care](#) to recognize and treat prenatal depression in order to support the mother and the child's development.

Altered brain connectivity may be one way prenatal depression influences child behavior, according to new research in *JNeurosci*.

Up to one fifth of women experience depression symptoms during pregnancy, with unknown effects on the fetus. Prenatal depression is correlated with behavioral and developmental issues in the child, as well as an increased risk of developing depression at age 18. But how prenatal depression leads to these changes remains unclear.

Hay et al. studied 54 mother/child pairs. Mothers answered a survey about their depression symptoms at several points during their pregnancy. The research team employed diffusion MRI, an imaging technique that reveals the strength of structural connections between brain regions, to examine the children's [white matter](#).

Greater prenatal depression symptoms were associated with weaker white matter connections between [brain regions](#) involved in emotional processing. This change could lead to
