

Mammography screening saves lives also in older age

Mammography, which is an X-ray picture of the breast, is efficient also for women over the age of 70. For women invited to regular mammography screening over the age of 70, the reduction in mortality rate was significant. This according to a vast new study from Sweden.

"The results confirm that the Swedish assessment of setting the upper age limit for [mammography screening](#) to 74 was justified," says Håkan Jonsson, docent at the Department of Epidemiology and Global Health at Umeå University.

This new Swedish study builds upon twenty years of follow ups and over 2,000 breast [cancer](#) deaths. It turned out that the breast cancer mortality rate was 20 per cent lower for [women](#) invited to partake in [mammography](#) between the ages of 70 and 74 compared to those who were only invited up until

the age of 69. For those who actually took part in [screening](#), the mortality rate reduction was a full 27 per cent.

Mammography screening was introduced in the late 1980s after positive results from a number of randomized controlled trials of which several were conducted in Sweden. However, there have previously been uncertainties regarding what [age groups](#) should be included. As a result, countries have made different assessments and the recommendations have varied.

Currently, most countries offer screening for women up until the age of 69, but some countries—Sweden included—have chosen to set the upper age limit to 74. In Sweden, the screening programs are decentralized which has meant that the upper age limit of 74 has been introduced at different points in the various parts of the country. This not least as the early recommendations from the Swedish National Board of Health and Welfare allowed regional exceptions of an upper age limit of 69.

In the current study, the breast cancer mortality rate in women in the areas of Sweden that used an upper age limit of 74 were compared to those regions that used an age limit of 69 between the years 1986 and 2012. The Cancer Register was used to identify women diagnosed with breast cancer aged 70-74 and the National Cause of Death Register was used to gain data on cause of [death](#) for those who died from breast cancer aged 70-89. Cause of death may be difficult to decide—particularly for older women. Consequently, the excess mortality in [breast](#) cancer cases was measured in conjunction with the underlying cause of death.

"Given that we live longer and remain active in old age, it is also valuable to screen for cancer in order to start treatment in time," says Håkan Jonsson.

Most randomized controlled trials were conducted about 40 years ago. Only one of those trials included women aged 70 to 74. Nevertheless, this group was too small to provide any clear evidence. Observational studies are rare in this age group as few countries have invited these women to screening. This also means that the evidence of the importance of mammography in women aged 70 to 74 has been scarce until now.
