HTN visits vary for adults living in urban, rural residences
12 November 2020

The percentage of physician visits by adults with diagnosed hypertension varies by patient residence, according to a study published online Nov. 12 in the National Health Statistics Reports, a publication from the U.S. Centers for Disease Control and Prevention.

Danielle Davis, M.P.H., and Pinyao Rui, M.P.H., from the National Center for Health Statistics in Hyattsville, Maryland, used data from the 2014 to 2016 National Ambulatory Medical Care Survey to describe urban-rural differences in office-based physician visits by adults with documented hypertension.

The researchers found that the percentage of visits by adults aged 18 years and older with diagnosed hypertension was lower for those who lived in large metro suburban areas versus small-medium metro areas and rural areas (34.2 percent versus 37.9 and 40.1 percent, respectively). The percentage of visits was higher for men versus women with hypertension overall (41.0 versus 33.5 percent).
