

Fighting dementia with play: Cognitive motor training improves function

9 April 2021

Dementia turns the world upside down, not only for the person affected, but also for their relatives, as brain function gradually declines. Those affected lose their ability to plan, remember things or behave appropriately. At the same time, their motor skills also deteriorate. Ultimately, dementia patients are no longer able to handle daily life alone and need comprehensive care. In Switzerland alone, more than 150,000 people share this diagnosis, and each year, a further 30,000 new cases are diagnosed.

To date, no pharmaceutical approach to dementia has been developed. Dementia, including Alzheimer's—the most common of several forms of dementia—remains incurable. However, a [clinical study](#) carried out in Belgium with the involvement of ETH researcher Eling de Bruin has now shown for the first time that cognitive motor training improves both the cognitive and physical skills of significantly impaired dementia patients. A fitness game known as Exergame, developed by the ETH spin-off Dividat, was used in the study.

Better cognitive ability thanks to training

In 2015, a team of scientists led by ETH researcher Patrick Eggenberger showed that older people who train both body and mind simultaneously demonstrate better cognitive performance and can thereby also prevent cognitive impairment (as reported by ETH News). However, this study was carried out on healthy subjects only.

"It has been suspected for some time that physical and cognitive training also have a [positive effect](#) on dementia," explains de Bruin, who worked with Eggenberger at the Institute of Human Movement Sciences and Sport at ETH Zurich. "However, in the past, it has been difficult to motivate dementia patients to undertake physical activity over extended periods."

ETH spin-off combines exercise and fun

With a view to changing this, Eva van het Reve, a former ETH doctoral student, founded the ETH spin-off Dividat in 2013 together with her Ph.D. supervisor Eling de Bruin and another doctoral student. "We wanted to devise a customized training program that would improve the lives of older people," says van het Reve. Fun exercises were developed in order to encourage people who were already experiencing physical and cognitive impairments to participate in training, and the Senso training platform was born.

The platform consists of a screen with the game software and a floor panel with four fields that measure steps, weight displacement and balance. The users attempt to complete a sequence of movements with their feet as indicated on the screen, enabling them to train both physical movement and cognitive function simultaneously. The fact that the fitness game is also fun makes it easier to motivate the subjects to practice regularly.

Eight weeks' training for dementia patients

An international team led by Nathalie Swinnen, a

doctoral student at KU Leuven, and co-supervised by ETH researcher de Bruin, recruited 45 subjects for the study. The subjects were residents of two Belgian care homes, aged 85 years on average at the time of the study and all with severe dementia symptoms.

"The participants were divided into two groups on a random basis," explains de Bruin. "The first group trained for 15 minutes with the Dividat Senso three times a week for eight weeks, while the second group listened to and watched music videos of their choice." Following the eight-week training program, the physical, cognitive and mental capacity of all subjects was measured in comparison with the start of the study.

Regular play has an effect

The results offer hope to dementia patients and their relatives: training with this machine indeed enhanced cognitive skills, such as attention, concentration, memory and orientation. "For the first time, there's hope that through targeted play we will be able not only to delay but also weaken the symptoms of dementia," emphasizes de Bruin.

It is particularly striking that the control group deteriorated further over the eight-week period, while significant improvements were recorded in the training group. "These highly encouraging results are in line with the expectation that [dementia patients](#) are more likely to deteriorate without training," adds de Bruin.

But playful training not only has a positive impact on cognitive ability—researchers were also able to measure positive effects on physical capability, such as reaction time. After just eight weeks, the subjects in the [training](#) group reacted significantly more quickly, while the control group deteriorated. This is encouraging in that the speed with which older people respond to impulses is critical in determining whether they can avoid a fall.

A better understanding of brain processes

The research group led by de Bruin is currently working on replicating the results of this pilot study with people with mild [cognitive impairment](#)—a

precursor of [dementia](#). The aim is to use MRI scans to investigate more closely the neural processes in the brain responsible for the cognitive and physical improvement.
