A new study from Lund University in Sweden on how the Pfizer-BioNTech COVID-19 vaccine affects human liver cells under experimental conditions, has been viewed more than 800,000 times in just over a week. The results have been widely discussed across social media—but the results have in many cases been misinterpreted. Two of the authors, Associate Professor Yang de Marinis (YDM) and Professor Magnus Rasmussen (MR), share their views.

How did this study come about?

YDM: A previous study from MIT has indicated that the SARS-CoV-2 virus mRNA can be converted to DNA and integrated into the human genome. Indeed, about 8 percent of human DNA comes from viruses inserted into our genomes during evolution. Does the Pfizer-BioNTech mRNA vaccine get converted to DNA or not? This has been the question our study aims to answer.

What are key limitations of the study?

MR: One should consider that cell lines differ from cells in living organisms, and therefore it is important that similar investigations are also studied in humans.

It is important to bear in mind that the liver cells in this study are more genetically unstable than our own liver cells.
don't know if what we observed in this cell line could also happen in cells of other tissue types, and this needs to be addressed in follow-up studies.

**The study has received a lot of media attention, what are your thoughts on that?**

MR: We understood that the study would attract attention, but we think it is self-evident that this type of research should be pursued. We have a new vaccine, and it needs to be tested in cell and animal models and also in humans, in various ways. The result might be surprising, but it is also a bit surprising that such studies do not seem to have been carried out before.

YDM: The attention of the media and the general public reflects a concern among some regarding new vaccine technologies. This in itself motivates the need for further studies.

**Based on this study, is there any reason to not get vaccinated?**

MR: There is no reason for anyone to change their decision to take the vaccine based on this study.

**What are the next steps in this research?**

YDM: More research is needed. Data, especially data from vaccinated humans, will hopefully sort out the question marks. Whether our results are true for other cell types in humans, or if they are specific to mRNA vaccines, are among many questions for further research.

**About the study:**

In a lab environment, i.e., in petri dishes, the researchers added Pfizer BioNTech's vaccine to a cell line that originally came from a human liver tumor.

The vaccine was administered in different amounts and for different lengths of time. Cells that received no vaccine at all were used for control purposes. The researchers then investigated how different gene expressions in the cells changed over time. A gene that the researchers studied produces the protein LINE-1.
